

Bias Detection Report

The bias type is Correlation.

The relevant features are Age and Sex.

The results from the tools indicate that there is a moderate level of bias between Age and Sex.

For example, the Hilbert-Schmidt Independence Criterion (HSIC) method calculated a value of 0.005, which indicates a moderate level of correlation bias.

While this level of bias does not fully compromise the dataset's usability, you may need to consider this bias in certain applications.

I recommend giving these results additional thought before proceeding.
