Bias Detection Report

This is a report introduction.

The bias type is correlation bias between two categorical features, specifically education and race. The relevant features are education and race. The bias level is Level 1, which indicates a weak association between the features.

To provide a more detailed explanation, Cramér's V was calculated to be 0.06699264949915482, which is less than 0.1. This indicates that the association between education and race is relatively weak.

Based on the results, it can be concluded that there is a weak correlation bias between education and race in the Adult dataset. This means that the education level and race of an individual are not strongly associated with each other.
